Association of pre-operative ankle brachial index with hospital mortality in patients undergoing endovascular and open repair of the descending thoracic aortic aneurysm. Endovascular stent graft repair of descending thoracic aortic aneurysms has reduced the morbidity and mortality compared to open repair. However, the relationship between pre-operative ankle brachial index (ABI) and hospital mortality after endovascular repair of aortic aneurysms is not well established. This study was conducted to assess the impact of ABI on hospital mortality after endovascular stent grafting of aneurysms and to compare the hospital mortality between endovascular stent grafting and open repair. The data of patients treated for aortic aneurysms at a single centre from January 2002 to August 2012 were retrospectively analysed. Patients were grouped according to the procedure they underwent: aortic endovascular repair (EVAR) and open repair (OR). We analysed the hospital mortality and its association with pre-operative ABI. The multivariate logistic regression analysis was used to control for potential confounders. Overall, 251 patients were included in the study. The median age was 73.0 (range: 48-87) years, and 144 patients were men. EVAR was performed in 116 patients and OR in 135 patients. The hospital mortality rate was 2.1% (5/251). EVAR had a significantly lower hospital mortality than OR (2d92ce491b
