Diffuse idiopathic skeletal hyperostosis (DISH) is characterized by a characteristic radiologic appearance of hypertrophic osteoarthropathy. This report presents our experience with computed tomography (CT) in the diagnosis and management of DISH. The retrospective case series included 14 patients (seven men and seven women; mean age, 61.5 years; range, 36 to 80 years). The mean duration of symptoms was 6.7 years (range, 3 to 18 years). Of the 14 patients, 10 had clinically evident manifestations of DISH. Computed tomography showed enthesopathy at the sites of the insertion of the tendon of the tibialis posterior into the calcaneus (13 patients), at the site of the insertion of the tibialis anterior into the distal aspect of the calcaneus (11 patients), and at the insertion of the flexor tendons of the second and third digits into the distal aspect of the first metacarpal (four patients). The changes were unilateral in all patients except two, and were multiple in eight patients. All patients had either prior or simultaneous vertebral compression fractures. Plain radiography was performed on 12 patients and showed typical radiologic findings. Computed tomography of the thoracic spine (nine patients) was performed to exclude spinal stenosis. It showed that the hyperostotic 2d92ce491b
